

# Higher-Order Functions in Haskell

## Basic Combinators

| Combinator  | CL | Haskell | Type |
|-------------|----|---------|------|
| Identity    |    |         |      |
| Constant    |    |         |      |
| Exchange    |    |         |      |
| Composition |    |         |      |
| Application |    |         |      |

## Higher-order Functions for Lists and Tuples

| Name      | Type | Description |
|-----------|------|-------------|
| map       |      |             |
| filter    |      |             |
| zipWith   |      |             |
| dropWhile |      |             |
| takeWhile |      |             |
| curry     |      |             |
| uncurry   |      |             |
| zip       |      |             |
| span      |      |             |

## One Recursive Function to Rule Them All

```
foldr ::  
  
foldr f b []      = b  
foldr f b (x:xs) = f x (foldr f b xs)
```

**Challenge Problem:** Define the functions `map`, `filter`, and `takeWhile` in one line using `foldr`. Your definitions should *not* be recursive: you should just call `foldr` with a proper lambda function.
